

Nithdale Station Andrew Tripp

- Your definition of IWG relates to spraying or cultivation and sowing of any feed and grazed so that the ground remains bare after the grazing. And you ask if this would this include grass areas where supplementary feed is fed out to stock in a concentrated situation so that the grass is removed and the ground becomes bare. What do you think the answer to this should be?
- Using a low percentage for risky PZ and a higher percentage for less risky PZ for IWG has been suggested by at least one other submitter. How would this work on a property where there were a number of small areas of risky soils?
- How do you propose testing the water to see if it is acceptable?
- Would the boggy areas where sheep get stuck be critical source areas that would be better fenced off to filter runoff from other areas of the farm?
